## Concepts

- A derivative is the slope of the tangent line at any point along a curve.
- Let  $x$  be a point on the curve and  $h$  be the distance between two points, then the mathematical formula for the slope as  $h$  approaches zero is given as:

$$f'(x) = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h}$$

- Differentiation is the process of finding a function's derivative.
- Finding the derivative of:  $f(x) = -(x)^2 + 3x - 1$ :

- $y' = \lim_{h \rightarrow 0} \frac{-(x+h)^2 + 3(x+h) - 1 - (-(x)^2 + 3x - 1)}{h}$

- $y' = \lim_{h \rightarrow 0} \frac{-x^2 - 2xh - h^2 + 3x + 3h - 1 + x^2 - 3x + 1}{h}$

- $y' = \lim_{h \rightarrow 0} \frac{h(-2x - h + 3)}{h}$

- $y' = \lim_{h \rightarrow 0} -2x - h + 3$

- $y' = -2x + 3$

- Three ways of notating a curve's derivative:

- $y' = -2x + 3$

- $f'(x) = -2x + 3$  \*Only use if derivative is a function

- $\frac{d}{dx}[-x^2 + 3x - 1] = -2x + 3$

- A critical point is a point where the slope changes direction from negative slope to positive slope or vice-versa. Critical points represent extreme values, which can be classified as a minimum or extreme value.

- Critical points are found by setting the derivative function to 0 and solving for  $x$

- Critical point classification:

- When the slope changes direction from positive to negative it can be a maximum value.

- When the slope changes direction from negative to positive, it can be a minimum value.

- If the slope doesn't change direction, like at  $x = 0$  for  $y = x^3$ , then it can't be a minimum or maximum value.

- Each maximum or minimum value points are known as local extrema.

- Classifying local extrema:

- A point is a relative minimum if a critical point is the lowest point in a given interval.

- A point is a relative maximum if a critical point is the highest point in a given interval.

- Instead of using the definition of the derivative, we can apply derivative rules to easily calculate the derivative functions.

- Derivative rules:

- Power rule: Let  $r$  be some power, then  $f'(x) = rx^{r-1}$

- Example: Let  $f(x) = x^2$  In our function,  $r$  would be 2. Using the power rule, it's derivative would be  $f'(x) = 2x^{2-1}$  or  $f'(x) = 2x$

- Sum rule:  $\frac{d}{dx}[f(x) + g(x)] = \frac{d}{dx}[f(x)] + \frac{d}{dx}[g(x)]$

- Example:  $\frac{d}{dx}[-x^3 + x^2] = \frac{d}{dx}[-x^3] + \frac{d}{dx}[x^2] = -3x^2 + 2x$

- Constant factor rule:  $\frac{d}{dx}[3x] = 3 \frac{d}{dx}x = 3 \cdot 1 = 3$
- Derivative of  $x$  is always 1 and derivative of 1 is always 0.
- Once you found the critical points of a function, you can analyze the direction of the slope around the points using a sign chart to classify the point as a minimum or maximum. We can test points around our points of interest to see if there is a sign change as well as what the change is.
